Agentic AI

🔹 **Problem Statement 1 Pitch**

Autonomous Research Intelligence Agent (ScholAR)

"Today, researchers can find papers in seconds… but understanding how those papers connect — what's important, what's missing, and what to read next — still takes weeks.
Existing tools can show connections, but they stop at visualization. They don't generate insights. They don't guide decisions.
In this challenge, participants are expected to build **ScholAR — an autonomous research intelligence agent**.
This system should take a simple input like a research topic or paper… and automatically:

- Build a **knowledge graph of related research**
- Identify key papers, trends, and clusters
- Detect research gaps and contradictions
- And finally generate a **complete literature review report**

Most importantly, the system must **decide on its own** —
what to search, what to include, when to stop, and how to present insights.
This is not just search… this is **automated research thinking."

🔹 **Problem Statement 2 Pitch**

Persistent Memory for Long-Running Agents

"Most AI systems today have a major limitation — they forget.
They cannot remember what happened yesterday, they cannot build long-term understanding, and they often rely on large prompts, which leads to inconsistency and hallucination.
In this challenge, participants are expected to solve what is called the **'Amnesia Problem' in AI systems**.
They will design a system that allows an AI agent to:

- Store important information over time
- Retrieve it intelligently when needed
- Update or remove outdated knowledge
- And detect contradictions in its own memory

The goal is to build an agent that can **think across sessions**, not just in a single interaction.
This is about building **trustworthy, long-term intelligent systems**, where memory is structured, reliable, and explainable."

◆ **Problem Statement 3 Pitch**

AI Legal Document Action Agent

"Legal documents are something everyone signs… but very few truly understand.
From rental agreements to terms and conditions, these documents are filled with complex language, creating a gap between what users sign and what they actually understand.
In this challenge, participants are expected to build an **AI system that simplifies and explains legal documents in a meaningful way**.
The system should:

- Break down complex legal text into simple language
- Highlight risks, obligations, and important clauses
- Allow users to ask questions and get clear answers
- And help users make informed decisions

But beyond summarization, the system should act like a **smart assistant** —
one that guides the user, identifies risks proactively, and supports decision-making.
This is about making legal understanding **accessible, safe, and actionable for everyone."
